Centre for Marine Science and Technology, Manonmaniam Sundaranar University, Rajakkamangalam, Kanyakumari, Tamilnadu, India-629502.

*Bacillus cereus* TC-1 was isolated from condenser pond of manmade solar salt pan Thamaraikulam, Tamilnadu, India effectively suppressed the shrimp bacterial pathogens *Vibrio harveyi*, *V. parahaemolyticus*, *V. anguillarum*, *V. alginolyticus* and *V. vulnificus* by in vitro antagonistic assay of 9 to 15 mm of zone of inhibition. Phylogenetic analysis revealed that, *B. cereus* TC-1 was highly similar that the *B. thuringiensis* strain (100%) and other *Bacillus* sp. Their optimum growth between at the range of 4 to 6% of NaCl in the growth media and significantly (P<0.05) high alkaline protease production (170.85 U/ml) was observed in the NaCl of 6 %. Based on the antagonistic activity of the *B. cereus* TC-1 against the shrimp pathogens and its antimicrobial factors, it may be used as probiotics and developing novel antimicrobial bioactive substances against aquatic pathogens.

**Keywords:** Antagonism, *Bacillus cereus*, Extremophiles, Halophilic Bacteria

**Introduction**

Microbes from extreme environments have attracted considerable attention in recent years. This is primarily due to the secret that they hold about the molecular evolution of life and stability of the macromolecules\(^1\). They are often under extreme conditions of e.g., pressure, temperature, salinity, and depletion of micronutrients, with survival and proliferation often depending on the ability to produce biologically active compounds. The diversity of marine environments has exerted a driving force on bacteria selection leading to new adaptive strategies and the synthesis of new metabolites\(^2\). Microbial secondary metabolites have been recognized as a major source of compounds endowed with ingenious structures and potent biological activities\(^3\).

The genus *Bacillus* constitutes a diverse group of rod-shaped, Gram-positive bacteria, characterized by their ability to produce a robust spore. Most Bacillus species are not harmful to mammalians, including humans and are commercially important as producers of a high and diverse amount of secondary metabolites (antibiotics, bio insecticides, fine chemicals and enzymes)\(^4,5\). The genus *Bacillus* has been in use in the biotechnology industry for a very long time with a number of new cultures exhibiting a variety of benefits to humans. Members of the Bacillus genus are often considered microbial factories for the production of a vast array of biologically active molecules potentially inhibitory for phytopathogen growth, such as kanosamine or zwittermycin A from *B. cereus*\(^6\).

Microorganisms represent the most common candidates as sources of new enzymes because of their broad biochemical diversity, feasibility of mass culture and ease of genetic manipulation. Microbial alkaline proteases dominate the worldwide enzyme market, with a two third share of the detergent industry\(^7,8\). Nowadays increasing emphasis is being laid on extremophiles for the presence of such enzymes, mainly due to the mechanisms and strategies that help them to function under stressful growth conditions\(^9\).

Antagonistic activities between micro-organisms have been widely reported\(^10\) and in many instances the inhibition is due to the production of bacteriocins and other Extra Cellular Products (ECP). Bacteria showing antagonistic activity have potential application as bio control agents. Sugita *et al*\(^11\) isolated a strain of *Bacillus* sp. that was antagonistic to 63% of the bacterial isolates from fish intestine. Some bacteria have been observed to be antagonistic to even viruses\(^12\) and such bacteria have potential use in biocontrol of viral diseases\(^13\). The present study focuses isolation, identification, biochemical characterization and antagonistic studies of the halophilic *Bacillus cereus* from the crystallizer pond of the solar salt works.

**Materials and Methods**

Water samples were collected from the condensed ponds (C-I,II & III) from the solar salt works of Thamaraikulam, Kanyakumari, Tamilnadu, India. The physicochemical parameters of the samples were studied following the standard methods by Bhaskaran\(^14\) and given in the Table 1.
Saline water samples were decimally diluted and spread in the specific media Bacillus cereus Agar Base (Himedia, Mumbai, India) and incubated the plates at 37°C for 24 hours. A total number of 3 tentative isolates picked based on morphological characteristics and checked by microscopy (gram staining and spore staining) tested for motility and for presumptive identification.

The presumptive isolates subjected to biochemical characterization were based on sugar fermentation pattern in basal broth medium as per the standard method. The Bacillus isolates were tested using 15 carbohydrate discs (Himedia, Mumbai) for their ability to ferment different sugars. Isolates were also tested for catalase, indole, gelatin hydrolysis and lactic acid production.

Genomic DNA isolated from B. cereus TC-1 strain and 100 ng was PCR amplified using 16S rRNA universal primers. The PCR product was cloned in to pTZ57R vector and transformed to DH5α following the method of Sambrook et al. The transformants were sequenced by using ABI 3700 automated DNA sequencer. Sequences were compared with other 16S rRNAs obtained from Genbank using the BLAST program. Phylogenetic tree was constructed by clustal algorithm using Gene Bee software values were determined.

To optimize the B. cereus TC-1 growth in different NaCl concentration, Nutrient Broth was enriched with 1, 2, 3, 4 and 5 % NaCl and studied the growth curve. The inoculated cultures were incubated at 37°C in a shaker at 100 rpm and bacterial growth was monitored at 0, 12, 36, 48, 60, 72, 84 and 86 h after inoculation.

Alkaline protease assay was done in the skim milk agar base and the activity was estimated by Hagihara. The enzyme (0.5 ml) was added to 3.0 ml casein (0.6% w/v in 20 mM borax NaOH buffer, pH 10) and the reaction mixture was incubated at 37°C for 10 min before the addition of 3.2 ml of TCA mixture (0.11 M trichloroacetic acid, 0.22 M sodium acetate, 0.33 M acetic acid). The terminated reaction mixture was incubated for 30 min at room temperature. The precipitates were removed by filtration through Whatman no. 1 filter paper and the absorbance of the filtrate was measured at 280 nm. One unit of alkaline protease activity was defined as the amount of enzyme liberating 1 lg of tyrosine per minute under assay conditions. Enzyme units were measured using tyrosine (0–100 μg) as standard.

A lawn culture of the pathogenic Vibrio harveyi, V. parahaemolyticus, V. anguillarum, V. alginolyticus and V. vulnificus were prepared by pouring 2 ml of each young culture over Muller-Hinton Agar media plates, separately. Air dried the plate by keeping it in the incubator at 30°C for 15 minutes. Three millimeter diameter wells were punched in the plates using a sterile gel puncher. Thirty microlitres of an 18 hour culture of B. cereus TC-1 (16-18 hours in nutrient broth, supplemented with 5 % sodium chloride) was pipette into the wells and plates were incubated for 24 hrs. Zone of inhibition around the wells was recorded.

One way and two way Analysis of Variance (ANOVA) were carried out using the software PASW statistics data editor and Ky plot respectively. Means were compared at 0.05 % for One Way ANOVA and 0.001 % level.

**Results and Discussion**

Based on the morphological, physiological, biochemical and genetic identification, the rod shaped bacteria was confirmed as Bacillus cereus and submitted to the NCBI gene bank, accession number is GU939623.1. Cluster algorithm of Gene Bee analysis revealed that, B. cereus TC-1 was highly similar that the B. thuringiensis strain (100%) (GeneBank acc. No: AM292032.1) followed by the Bacillus sp. (92%) (GeneBank acc. No: AY853168.1) and the least similarity, 72% of the B. thuringiensis strain (AY138289.1) (Figs 1 &2). Many types of bacterial species have been isolated from various salt environments such as soils and salterns including the Gram-negative halophilic like species of the genera Vibrio, Alteromonas, Acinetobacter, Marinomonas, Pseudomonas, and the genera Marinococcus, Donio et al. 28
Sporosarcina, Salinococcus and Bacillus. NaCl played an important role for the growth of *B. cereus* TC-1. The bacterial cells belong to 2% NaCl growth media reached the stationary phase at 24 hours with less number of bacterial counts. The concentration between 4-6% responsible for more number and reached the stationary phase around 48 hours and significantly increased (P<0.05). Also two way ANOVA revealed that the growth rate was varied significantly among the different groups (F= 4.4333; 32. 0493; P<=0.001). The concentrations such as 12 and 15 had very slow growth with less numbers of cells and this result revealed that the NaCl concentration 4 - 6 was the optimum (Fig 3). Recently Patel et al., isolated and identified the haloalkaliphilic, gram positive, aerobic, coccoid *Bacillus pseudofirmus* - Po2 by 16s rRNA sequencing analysis from the seawater sample in Gujarat, India. They also screened and optimized the production of alkaline protease using NaCl, nitrogen sources and metal ions etc.

Figure 4a shows the positive alkaline protease activity produced by *B. cereus* TC-1 in the skimmed milk agar base. The clear zone indicated the hydrolysis of casein as a result of alkaline protease production. The lowest alkaline protease production was observed in 1 % NaCl of 92.24 U/ml. This was significantly (P<0.05) increased to 130.55 and 170. 85 respectively in the 2 and 3 % NaCl enriched growth media. Further the production was decreased the 4 to 6 % NaCl enriched growth media (Fig 4b). Patel et al., optimized the growth of haloalkaliphilic *Bacillus pseudofirmus* - Po2 at 10 % (w/v) NaCl and declared that the halotolerant nature of the strain Po2. Similar trends were also evident in *Salinicoccus alkaliphilus* sp., a moderately halophilic and alkaliphilic coccus isolated form Baer Soda Lake in Mongolia, which could grow over a wide range of NaCl, 0–25% (w/v) with optimum at 10% (w/v) NaCl. The present study, alkaline protease production also higher in 4 (130.55U/ml) and 6 % (170.85U/ml) NaCl enriched growth media and it reflected that due to the halophilic nature of the bacterial strain. The lower and higher concentrations are failed to attain more enzyme production. Po2 produced protease in the range of 5–20% (w/v) NaCl, optimally (162–170 U/ml) at 10% (w/v) NaCl. Similar results have also been reflected by the haloalkaliphilic archaeon, *Natronococcus occultus* in which protease secretion was optimum at 1–2 M NaCl. However, in the case of the archaeabacterium *Halobacterium mediterranei*, a much higher salt requirement (25%, w/v) for serine protease secretion was reported.

*In vitro* antagonistic activity of *Bacillus cereus* TC-1 against the five pathogenic *Vibrio sp* was tabulated in Table 2 and the
Field trails and characterize the virulence factors at treatments against the aquatic pathogens in laboratory as well.

Bacillus strains exert harmful effects on shrimp or the release antibacterial substances. There is less evidence that against bacterial or viral disease in shrimp aquaculture; they strains are one of the most recognized beneficial bacteria used decreased the bacterial loads in the culture tanks.

Suppressed the pathogenic activities against a variety of microorganisms. Bacteriocins have been studied in different species including: Bacillus subtilis, B. stearothermophilus, B. licheniformis, B. subtilis and other Bacillus sp.

Fig 5. The highest inhibitory activity was shown against *V. harveyi* (15.33±1.57 mm). The lowest activity was against *V. vulnificus* (9.25±0.85). The activity against other species likes *V. parahaemolyticus*, *V. anguillarum* and *V. alginolyticus* were 12.87±1.64, 11.05±0.77 and 13.33±1.24 mm respectively. *Bacillus* is an interesting genus to investigate for antimicrobial activity since *Bacillus* species production a diverse array of antimicrobial peptides representing several different basic chemical structures, with a distinct diversity in their inhibitory activities against a variety of microorganisms. Bacteriocins have been studied in different species including: *B. subtilis*, *B. cereus*, *B. stearothermophilus*, *B. licheniformis*, *B. thuringiensis* and other *Bacillus* sp.
