On the Study of Jacobi Fields in Riemannian Manifolds

Khondokar M. Ahmed

Department of Mathematics, University of Dhaka, Dhaka-1000, Bangladesh

Abstract

A new approach of finding a Jacobi field equation with the relation between curvature and geodesics of a Riemannian manifold $M$ has been derived. Using this derivation we have made an attempt to find a standard form of this equation involving sectional curvature $K$ and other related objects.

Key words: Riemannian curvature, Sectional curvature, Jacobi equation, Jacobifield.

Introduction

The concept of differentiating a vector field is not an "intrinsic" geometric notion on $M$. To remedy this state of affairs we consider, instead of usual derivative $\frac{dV}{dt}$, the orthogonal projection $\frac{dV}{dt}$ of on $T_{c(t)}M$. This orthogonal projected vector we call the covariant derivative and it is denoted by $\frac{dV}{dt}$. Jacobi fields are vector fields which is defined by the way of a differential equation which is developed in the study of the exponential mapping (Gauss 1965, Klingenberg 1959). The curvature $\kappa(p, \sigma)$, $\sigma \subset T_pM$ determines the fastness of the Geodesics. Some aspects of exponential mapping, symmetry property for symmetric connection on a parametrized surface, parametrized surface related with exponential mapping, curvature $R$ of a Riemannian manifold $M$, sectional curvature, constant sectional curvature, relation between trilinear mapping $R$ and the curvature $R$ will be treated in this present paper (Riemann 1959, Rauch 1953, Myers 1941). Finally we shall find a standard Jacobi equation with a solution.

Preliminaries

Definition 2.1 An inner product of a manifold $M$ at a point $p \in M$ is a symmetric, bilinear and positive definite form and is denoted by $\langle , \rangle_p$.

If $\psi : U \subset \mathbb{R}^n \rightarrow M$ is a system of coordinates around $p$ with $(x_1, x_2, \ldots, x_n) = q \in \psi(U) \subset M$ and $\frac{\partial}{\partial x_i}(q) = d\psi_q(0, \kappa, i, \kappa, 0)$ then
\[ < \frac{\partial}{\partial x_i}(q), \frac{\partial}{\partial x_j}(q) >_q = g_{ij}(x_1, \ldots, x_n) \] is a differentiable function on \( U \). We can delete the index \( p \) in the function \( <,>_p \) if there is no confusion.

**Definition 2.2** A parametrized curve \( \gamma : I \to M \) is a geodesic at \( t_0 \in I \) if
\[
\frac{D}{dt} \left( \frac{dy}{dt} \right) = 0
\]
at the point \( t_0 \), if \( \gamma \) is a geodesic at \( t \), for all \( t \in I \), we say that \( \gamma \) is a geodesic. If \([a, b] \subset I \) and \( \gamma : I \to M \) is a geodesic then the restriction of \( \gamma \) to \([a, b] \) is called a geodesic segment joining \( \gamma(a) \) to \( \gamma(b) \).

The tangent bundle \( TM \) is the set of pairs \((q, v)\), \( q \in M \), \( v \in T_qM \). If \((U, x)\) is a system of coordinates on \( M \), then any vector in \( T_qM \), \( q \in x(U) \), can be written as \( \sum_{i=1}^n v_i \frac{\partial}{\partial x_i} \).

Taking \((x_1, \ldots, x_n, y_1, \ldots, y_n)\) as coordinates of \((q, v)\) in \( TU \), it is easy to obtain a differential structure for \( TM \). The tangent bundle \( TU = U \times \mathbb{R}^n \) is locally a product. The canonical projection \( \pi : TM \to M \) given by \( \pi(q, v) = q \) is differentiable.

**Theorem 2.3** If \( X \) is a \( C^\infty \) vector field on the open set \( V \) in the manifold \( M \) and \( p \in V \) then there exist an open set \( V_0 \subset V \), \( p \in V_0 \), a number \( \delta > 0 \) and a \( C^\infty \) mapping \( \phi : (-\delta, \delta) \times V_0 \to V \) such that the curve \( t \to \phi(t, q) \), \( t \in (-\delta, \delta) \) is the unique trajectory of \( X \) which att the instant \( t = 0 \) passes through the point \( q \), for every \( q \in V_0 \) (do Carmo 1976).

The mapping \( \phi : V_0 \to V \) given by \( \phi(q) = \phi(t, q) \) is called the flow of \( X \) on \( V \).

**Definition 2.4** The vector field \( G \) on \( TM \) whose trajectories are of the form \( t \to (\gamma(t), \dot{\gamma}(t)) \) is called the geodesic field on \( TM \) and its flow is called the geodesic flow on \( TM \).

**Proposition 2.5** Given \( p \in M \), there exist an open set \( V \subset M \), \( p \in V \), number \( \delta > 0 \) and \( \varepsilon > 0 \) and a \( C^\infty \) mapping \( \gamma : (-\delta, \delta) \times U \to M \), \( U = \{(q, v) \mid q \in V, v \in T_qM, \mid v \mid < \varepsilon \} \), such that the curve \( t \to \gamma(t, q, v) \), \( t \in (-\delta, \delta) \) is the unique geodesic of \( M \) which at the instant \( t = 0 \), passes through \( q \) with velocity \( v \), for each \( q \in V \) and for each \( v \in T_qM \) with \( \mid v \mid < \varepsilon \).

**Lemma 2.6** (Rauch 1953) (Homogeneity of a geodesic) If the geodesic \( \gamma(t, q, v) \) is defined on the interval \((-\delta, \delta)\) then the geodesic \( \gamma(t, q, av) \) \( a \in \mathbb{R} \), \( a > 0 \), is defined on the interval \((-\delta/a, \delta/a)\) and \( \gamma(t, q, av) = \gamma(at, q, v) \).

**Definition 2.7** Let \( p \in M \) and let \( U \subset TM \) be an open set given by \( U = \{(q, v) \in TM \mid q \in V, v \in T_qM, \mid v \mid < \varepsilon \} \). Then the map \( \exp : U \to M \) given by
\[
\exp(q, v) = \gamma(1, q, v) = \gamma \left( \frac{v}{\mid v \mid}, \frac{q}{\mid q \mid} \right), (q, v) \in U
\]
is called the exponential map on \( U \).

Clearly, \( \exp \) is differentiable. In the application we shall use the restriction of \( \exp \) to
an open subset of the tangent space $T_qM$ and we define

$$\exp_q : B_\varepsilon (0) \subset T_qM \to M$$

by $\exp_q (v) = \exp (q, v)$, where $B_\varepsilon (0)$ is an open ball with center at the origin $O$ of $T_qM$ and of radius $\varepsilon$. We can prove that $\exp_q$ is differentiable and $\exp_q (0)$.

**Proposition 2.8** Given $q \in M$, there exists an $\varepsilon > 0$, such that $\exp_q : B_\varepsilon (0) \subset T_qM \to M$ is a diffeomorphism of $B_\varepsilon (0)$ onto an open subset of $M$.

**Minimizing Properties of Geodesics**

**Definition 3.1** A piecewise differentiable curve is a continuous mapping $c : [a, b] \to M$ of a closed interval $[a, b] \subset \mathbb{R}$ into $M$ satisfying the following condition: there exists a partition $a = t_0 < t_1 < \ldots < t_k = b$ of $[a, b]$ such that the restrictions $c|_{[t_i, t_{i+1}]}$, $i = 0, \ldots, k-1$ are differentiable. We say that $c$ joins the points $c(a)$ and $c(b)$. $c(t_i)$ is called a vertex of $c$ and the angle formed by $\lim_{t \to t_i^+} c'(t)$ with $\lim_{t \to t_i^+} c'(t)$ is called the vertex angle at $c(t_i)$.

**Lemma 3.2** (do Carmo 1976) (Symmetry) If $M$ is a differentiable manifold with a symmetric connection and $S : A \subset \mathbb{R}^2 \to M$ is a parametrized surface then

$$\frac{D}{dt} \frac{\partial S}{\partial U} = \frac{D}{dt} \frac{\partial S}{\partial U}$$

**Lemma 3.3** (Rauch 1953) (Gauss) Let $p \in M$ and let $v \in T_p M$ such that $\exp_p v$ is defined. Let $w \in T_p M - T_v (T_p M)$. Then

$$< (d\exp_p)_v (v), (d\exp_p)_v (w) > = < v, w >$$

**Proof.** Let $w = w_t + w_N$, where $w_t$ is parallel to $v$ and $w_N$ is normal to $v$. Since $d\exp_p$ is linear and by the definition of $\exp_p$, it suffices to prove (1) for $w = w_N$. It is clear that we can assume $w_N \neq 0$.

Since $\exp_p v$ is defined, there exists $\varepsilon > 0$ such that $\exp_p$ is defined for $u = tv(s), \quad a \leq t \leq b, \quad -\varepsilon < s < \varepsilon$.

where $v(s)$ is a curve in $T_p M$ with $v(0) = v, v'(0) = w_N$ and $|v(s)|$ constant. Now, we can consider the parametrized surface (Ahmed 2004)

$$f : A \to M, A=\{t,s\} | 0 \leq t \leq 1, -\varepsilon < s < \varepsilon \}$$

given by $f(t,s) = \exp_p tv(s)$.

Observe that the curve $t \to f(t,s_0)$ are geodesics.

$$\frac{df}{ds} = (d\exp_p)_{v(t)} v'(s), \quad \frac{df}{dt} = (d\exp_p)_{v(t)} v'(s)$$

To prove (1) for $w = w_N$, observe first that by putting $t = 1, s = 0$

$$< \frac{df}{ds}, \frac{df}{dt} > | (1,0) = < (d\exp_p)_v (w_N), (d\exp_p)_v (v) >$$

In addition, for all $(t, s)$, we have

$$\frac{\partial}{\partial t} < \frac{\partial f}{\partial s}, \frac{\partial f}{\partial t} > = < \frac{\partial f}{\partial s}, \frac{\partial f}{\partial t} > + < \frac{\partial f}{\partial s}, \frac{\partial f}{\partial t} >$$

The last term of the above expression is zero,
since \( \frac{df}{dt} \) is the tangent vector of a geodesic. From the symmetry of the connection, the first term of the sum is transformed into
\[ < \frac{df}{ds}, \frac{df}{dt} > = < \frac{df}{ds}, \frac{df}{dt} > - \frac{1}{2} \frac{d}{dt} < \frac{df}{ds}, \frac{df}{dt} > = 0. \]
It follows that \( < \frac{df}{ds}, \frac{df}{dt} > \) is independent of \( t \). Since
\[ \lim_{t \to 0} \frac{df}{ds} (t, 0) \lim(d \exp_p)_{t \to 0} T_pM = 0. \]
we conclude that \( < \frac{df}{ds}, \frac{df}{dt} > (1, 0) = 0 \) which together with (2) proves the lemma.

**The Derivation of Jacobi Field Equation**

Let \( M \) be a Riemannian manifold and let \( p \in M \). In Gauss Lemma we saw that if \( \exp_p \) is defined at \( v \in T_pM \) and if \( w \in T_v(T_pM) \) then
\[ (d \exp_p)_v w = \frac{df}{ds} (t, 0), \]
where \( f \) is a parametrized surface given by \( f(t, s) = \exp_p tv(s), \quad 0 \leq t \leq 1, \quad -\varepsilon \leq s \leq \varepsilon \) and \( v(s) \) is a curve in \( T_pM \) with \( v(0) = v \), \( v'(0) = w \).

It is convenient to extend our object slightly and study the field
\[ (d \exp_p)_v t w = \frac{df}{ds} (t, 0) \]
along the geodesic \( \gamma(t) = \exp_p (tv), \quad 0 \leq t \leq 1. \)

The remark is that \( \frac{df}{ds} \) satisfies a differential equation. Since \( \gamma \) is a geodesic, we have
\[ D \frac{df}{dt} = 0, \quad \text{for all} \quad (t, s). \]

**Lemma 4.1** Let \( f : A \subset \mathbb{R}^2 \to M \) be parameterized surface and let \( (t, s) \) be the usual coordinates of \( \mathbb{R}^2 \). Let \( V = V(t, s) \) be a vector field along \( f \). For each \( (t, s) \), it is possible to define \( R \left( \frac{\partial f}{\partial s}, \frac{\partial f}{\partial t} \right) \) in a obvious following manner:
\[ \frac{D}{dt} \frac{D}{ds} V = \frac{D}{ds} \frac{D}{dt} V = R \left( \frac{\partial f}{\partial s}, \frac{\partial f}{\partial t} \right) \]

**Proof.** Consider a system \( (U, x) \) based at \( p \in M \). Let
\[ V = \sum_i v^i X_i, \quad (3) \]
where \( v^i = v^i (s, t) \) and \( X_i = \frac{\partial}{\partial x_i} \). Then
\[ \frac{D}{ds} V = \sum_i v^i \frac{DX_i}{ds} + \sum_i \frac{D v^i}{ds} X_i, \]
and
\[ \frac{D}{dt} \left( \frac{D}{ds} V \right) = \sum_i v^i \frac{DX_i}{dt} + \sum_i \frac{D v^i}{dt} X_i + \sum_i \frac{D^2 v^i}{ds dt} X_i, \quad (4) \]
By interchanging the coordinates \( s \) and \( t \) in the above expression, we obtain
\[ \frac{D}{ds} \left( \frac{D}{dt} V \right) = \sum_i v^i \frac{DX_i}{ds} + \sum_i \frac{D v^i}{ds} X_i + \sum_i \frac{D^2 v^i}{ds dt} X_i \]
\[ \frac{D}{dt} \left( \frac{D}{ds} V \right) = \sum_i v^i \frac{DX_i}{dt} + \sum_i \frac{D v^i}{dt} X_i + \sum_i \frac{D^2 v^i}{dt ds} X_i, \quad (5) \]
Now, subtracting (5) from (4), we obtain
\[
\frac{D}{dt}\left(\frac{D}{ds} V^i\right) - \frac{D}{ds}\left(\frac{D}{dt} V^i\right) = \sum_i v^j \left(\frac{D}{dt} \frac{D}{ds} X^i_j - \frac{D}{ds} \frac{D}{dt} X^i_j\right) \tag{6}
\]
since,
\[
\sum_i \frac{\partial}{\partial s} \frac{D}{dt} X^i_j = \sum_j \frac{\partial}{\partial t} X^i_j \quad \& \quad \sum_i \frac{\partial^2}{\partial t \partial s} X^i_j = \sum_j \frac{\partial^2}{\partial s \partial t} X^i_j.
\]
Next, we need to calculate \(\frac{D}{dt} \frac{D}{ds} X^i_j\).

Put \(f(s,t) = (x_1(s,t), x_2(s,t), \ldots, x_n(s,t))\).

Then \(\frac{df}{ds} = \sum_j \frac{\partial x_j}{\partial s} X^i_j\) and
\[
\frac{df}{dt} = \sum_k \frac{\partial x_k}{\partial t} X^i_j,
\]
where \(X^i_j = \frac{\partial}{\partial x^i_j}\) and \(X^i_k = \frac{\partial}{\partial x^i_k}\).

We calculate
\[
\frac{DX^i_j}{ds} = \nabla \sum_j \frac{\partial x_j}{\partial s} X^i_j = \sum_j \frac{\partial x_j}{\partial s} \nabla x^i_j X^i_j
\]
and
\[
\frac{D}{dt} \frac{D}{ds} X^i_j = \frac{D}{dt} \left(\sum_j \frac{\partial x_j}{\partial s} \nabla x^i_j X^i_j\right)
\]
\[
= \sum_j \frac{\partial^2 x^i_j}{\partial t \partial s} \nabla x^i_j X^i_j + \sum_j \frac{\partial x_j}{\partial s} \sum_k \frac{\partial x_k}{\partial x^i_j} \left(\nabla x^i_j X^i_j\right)
\]
\[
= \sum_j \frac{\partial^2 x^i_j}{\partial t \partial s} \nabla x^i_j X^i_j + \sum_j k \frac{\partial x_j}{\partial s} \frac{\partial x_k}{\partial t} \nabla x^i_j X^i_j \tag{8}
\]
In the similar way, we obtain
\[
\frac{D}{ds} \frac{D}{dt} X^i_j = \sum_j \frac{\partial^2 x^i_j}{\partial s \partial t} \nabla x^i_j X^i_j + \sum_j k \frac{\partial x_j}{\partial s} \frac{\partial x_k}{\partial t} \nabla x^i_j X^i_j \tag{9}
\]
Subtracting (9) from (8), we obtain
\[
\left(\frac{D}{dt} \frac{D}{ds} - \frac{D}{ds} \frac{D}{dt}\right) X^i_j = \sum_j k \frac{\partial x_j}{\partial s} \frac{\partial x_k}{\partial t} \nabla x^i_j \left(\nabla x^i_j X^i_j\right) - \nabla x^i_j \left(\nabla x^i_j X^i_j\right)
\]
\[
= \sum_j \frac{\partial x_j}{\partial s} \frac{\partial x_k}{\partial t} R(X^i_j, X^i_k) X^i_j \tag{using def. of curvature [1]}
\]
Hence, (6) implies that
\[
\frac{D}{dt} \frac{D}{ds} V^i - \frac{D}{ds} \frac{D}{dt} V = R\left(\frac{df}{ds}, \frac{df}{dt}\right) V
\]
Now, the lemma 4.1 gives
\[
\frac{D}{dt} \left(\frac{D}{ds} \frac{df}{dt}\right) - R\left(\frac{df}{ds}, \frac{df}{dt}\right) \frac{df}{dt} = \frac{D}{ds} \left(\frac{D}{dt} \frac{df}{dt}\right)
\]
\[
\frac{D}{dt} \frac{D}{ds} \frac{df}{dt} + R\left(\frac{df}{ds}, \frac{df}{dt}\right) \frac{df}{dt} = 0
\]
Putting \( \frac{df}{ds}(t,0) = J(t) \), we obtain that \( J \) satisfies the equation
\[
\frac{D^2 J(t)}{dt^2} + R(\gamma'(t), J(t))\gamma'(t) = 0 \tag{10}
\]
and the equation (10) is known as the Jacobi equation with the relation between curvature and geodesics of a Riemannian manifold \( M \).

**Definition 4.2** Let \( \gamma : [0,a] \rightarrow M \) be a geodesic in \( M \) (Kulkarni 1970). A vector field \( J \) along \( \gamma \) is said to be a Jacobi field if it satisfies the Jacobi equation (10), for all \( t \in [0,a] \).

A Jacobi field is determined by its initial conditions \( J(0), \frac{DJ}{dt}(0) \). Let \( e_i(t), e_j(t), ..., e_n(t) \) be parallel, orthonormal fields along \( \gamma \), we shall write (Ahmed 2004)
\[
J(t) = \sum_i f_i(t)e_i(t),
\]
\[
a_{ij} = \langle R(\gamma'(t), e_i(t))\gamma', e_j(t) \rangle, \quad i,j = 1,2, ..., n = \text{dim } M.
\]

Then
\[
\frac{D^2 J}{dt^2} = \sum_i f'_i(t)e_i(t)
\]
and
\[
R(\gamma', J)\gamma' = \sum_j \langle R(\gamma', J)\gamma', e_j \rangle e_j = \sum_{ij} f_i \langle R(\gamma', e_i)\gamma', e_j \rangle e_j
\]

[since \( J = \sum_i f_i e_i \)]

Therefore, the equation (10) is equivalent to the system
\[
f_j''(t) + \sum_i a_{ij} f_i(t) = 0, \quad j = 1,2, ..., n
\]
which is a linear system of the second order. For the given initial conditions \( J(0), \frac{DJ(0)}{dt} \), there exists a \( C^\infty \) solution of the system defined on \([0,a]\) and 2nd linearly independent Jacobi fields along \( \gamma \).

**Remark 4.3** We observe that \( \gamma(\theta) \) and \( t \gamma(\theta) \) are Jacobi fields along \( \gamma \). The first field has derivative zero and vanishes and the second field is zero if and only if \( t = 0 \). For these reasons, we shall consider Jacobi fields along \( \gamma \) that are normal to \( \gamma(\theta) \).

**Lemma 4.4** Let \( M \) be a Riemannian manifold and \( p \) be a point of \( M \). Define a tri-linear mapping (Ahmed 2003) \( R' : T_p M \times T_p M \times T_p M \rightarrow T_p M \) by
\[
\langle R'(X,Y,W), Z \rangle = \langle X, W \rangle \langle Y, Z \rangle - \langle Y, W \rangle \langle X, Z \rangle,
\]
for all \( X, Y, W, Z \in T_p M \). Then \( M \) has constant sectional curvature equal to \( K \) if and only if \( R = KR' \), where \( R \) is the curvature of \( M \).

Using the lemma 4.4, we have for all vectors
$T$ along $\gamma$

$$< R(\gamma', J) \gamma', T > = K \{ < \gamma', \gamma' > \langle J, T \rangle - < J, \gamma' > \langle \gamma', T \rangle \}$$

$$= K < J, T >$$

[since $< \gamma', \gamma' > = 1$ and $< \gamma, T > = 0$]

Hence, $R(\gamma, J) \gamma' = KJ$

As a result, the Jacobi equation can be written as

$$\frac{d^2 J}{dt^2} + KJ = 0 \quad (12)$$

which is the standard form of Jacobi equation with a Jacobi field $J$ and a constant sectional curvature $K$.

Let $w(t)$ be a parallel field along $\gamma$ with $< \gamma(t), w(t) > \geq 0$ and $|w(t)| = 1$. It is easy to verify that

$$J(t) = \begin{cases} 
\frac{\sin(t\sqrt{K})}{\sqrt{K}} & \text{if } K > 0 \\
\frac{\text{t}w(t)}{2} & \text{if } K = 0 \\
\frac{\sinh(t\sqrt{-K})}{\sqrt{-K}} & \text{if } K < 0 
\end{cases}$$

is a solution of (12) with initial conditions $J(0) = 0, J'(0) = w(0)$.

**Conclusion**

A new approach of Jacobi field equation and its solution have been derived in Riemannian manifolds by using exponential mapping, geodesics, Gauss lemma. Using this Jacobi field equation and its solution along geodesic $\gamma$, one can find expansion of $|J(t)|^2 = \langle J(t), J(t) \rangle$ about $t = 0$, the value of $\langle J(t), \gamma'(t) \rangle$ and other results which are involved with Riemannian curvature $R$.
