Original Article

Status of ToRCH positivity among the children presented with congenital Hydrocephalus

Mukherjee SK1, Afreen S2, Roy HA3, Khan RK4, Arman DM5, Hossain MA6, Ziauddin7, Ekramullah SM8, Rahman M9, Yousuf A10, Islam J11

Abstract:

Introduction: ToRCH is an acronym for four congenital infections that are sometimes difficult to distinguish: Toxoplasmosis, Rubella, Cytomegalovirus (CMV), and Herpes Simplex Virus (HSV). This group of organisms produces serious Central Nervous System (CNS) and other infections, which are potentially preventable and treatable.

Methods: Neonates and infants with hydrocephalus (N = 65) identified via the outpatient department of the National Institute of Neurosciences and Hospital (NINS&H), were prospectively screened for ToRCH antibodies. Hydrocephalus secondary to Tumor or Trauma was excluded from this study.

Results: Evidence of 75.38 % (p = <0.05) patient was positive for TORCH antibodies. Toxoplasma Gondi (T. Gondii) IgG 18.5 % (p = <0.05), CMV IgM 9.2 % (p = <0.05), CMV Ig G47.7% (p = <0.5), Rubella, and HSV 1 & 2 antibodies were also identified.

Conclusion: The vast majority of cases of neonatal hydrocephalus at one institution was post-infectious in etiology and related to ToRCH infections. Many of these cases could be prevented with improved screening and treatment. While study of a single institution may not be the representative of the entire population, further study and implementation of a standardized screening protocol would likely benefit this population.

Key Words: Congenital Infection, ToRCH, Hydrocephalus, Prevention, CMV, Toxoplasma.

Abbreviations:
CMV: Cytomegalovirus
CNS: Central Nervous System
HCP: Hydrocephalus
HSV: Herpes Simplex Virus
IRB: Institutional Review Board
NTD: Neural Tube Defect
PCR: Polymerase Chain Reaction
T. Gondi: Toxoplasma Gondii
TORCH: Toxoplasma Gondi, Rubella, CMV, Herpes
USG: Ultra sonogram

Introduction: ToRCH infections cause significant morbidity and mortality in neonates. Transplacental spread is the usual route of infection in neonates. Post-infectious hydrocephalus caused by congenital ToRCH infections is a significant source of morbidity and mortality, and its prevalence is known to vary by region. This pilot study was done to assess the association between Congenital HCP and ToRCH infection. Early diagnosis and treatment of congenital ToRCH infections leads to improved outcomes. In an Indian study in Hyderabad 28% T. Gondii was present and CMV was present in 92% population among pregnant woman. Post-infectious etiology has been shown to be more prevalent in low- and middle- income countries compared with high- income countries. Congenital toxoplasmosis may lead to a wide range of ocular and neurologic sequel, including hydrocephalus, although avoiding exposure to cats and uncooked meat can aid prevention. Toxoplasma tachyzoites are secreted into milk in various farm animals. Hydrocephalus has been estimated to affect approximately 4% of infants with congenital toxoplasmosis and is a significant cause of morbidity and mortality in this disease. The incidence of congenital rubella syndrome was significantly reduced over the last century due to vaccination. CMV is the most common cause (10-20%) of congenital infection in the United States. Such infants have a mortality rate of 12% by six months of age. Global prevalence of CMV infection in developed countries (45%) and developing countries (100%). Herpes simplex is most often acquired during delivery rather than during gestation, it is more preventable and treatable compared with CMV or Rubella.

Material and Method:

This was a prospective observational study, was conducted in Pediatric Neurosurgery department of National Institute of Neurosciences and Hospital (NINS&H), Dhaka, Bangladesh. Sixty five (65) patients were recruited from November 2017 to October 2018. Inclusion criteria were neonatal HCP age <1 year. Exclusion criteria were HCP associated with tumor, trauma, hemorrhage, arachnoid cyst, and Dandy Walker Malformation. As per inclusion & exclusion criteria we recruit sixty five (65) cases and do serological examination [ELISA, ERBA®, USA]. A literature review regarding ToRCH related HCP, including screening and treatment protocols was also performed. Data were analyzed for association between Neonatal HCP and Congenital ToRCH infection using SPSS17. Categorical Data were analyzed using one sample t test where p Value <0.05 was considered statistically significant. This study was approved by Institutional Review Board (IRB).

Results:

A total 65 cases of Congenital HCP recruited as per selection criteria. Among the 65 cases 75.38 % cases were ToRCH Positive (Fig.1). Most of the patients came from rural area, 56.9 % were male. The commonest age group was 31-90 days (41.5 %) (Fig. 2). The total age range was 26 days to 6 years. All three patients with concurrent encephalocele and all eight patients with concurrent myelomeningocele were also found to have congenital ToRCH infections.

Fig.-1: Pie Chart of ToRCH positive patient.

Fig.-2: Bar Chart for Age Distribution of ToRCH positive Patients.
T. Gondii IgM antibody was absent but 18.5% were T. Gondii IgG positive (p <0.05). Among the 12 cases of toxoplasma positive group 6 (50%) had contact with cat during pregnancy. Rubella IgM & IgG Antibody was present in 1.5% and 38.5 % respectively. As 86% of population under coverage of vaccination, so, antibody against Rubella may not important. 11(Fig 1b)

CMV IgM & IgG Antibody was present in 9.2% (p = < 0.05) and 47.7 % (p = < 0.05) respectively. HSV 1 IgM & IgG Antibody were present in 4.6% and 26.2% respectively. Herpes 2 IgM Antibody was absent but 9.2% patients were HSV 2 IgG Positive.

**Discussion:**

During the past 20 years, a number of scientific and sociological changes have altered the scenario of ToRCH infections. The incidence of these diseases has changed significantly because there are better preventive measures. The potentially significant relation between ToRCH infections and CNS anomalies including HCP and also Neural Tube Defects (NTDs) is now an important subject of investigation. Few previous articles address this issue. Although maternal TORCH infection is common in Bangladesh, India, Malaysia and Thailand. 12

The classic triad of *T. Gondii* infection is: Chorioretinitis, Hydrocephalus, Intracranial calcifications, and are present concurrently in 61.6% of cases. In 1982 Joksim et al did a study in Yugoslavia where they found 39% congenital HCP was *T. Gondii* positive, in our study 18.5% HCP was *T. Gondii* positive. 13 In 2015 Samuel Huston’s study demonstrated 4% congenital HCP associated with congenital *T. Gondii*. 14 Specific anatomical patterns of Toxoplasma infection commonly causes cerebral calcification and generalized periventricular inflammation (asymmetrical dilatation of the lateral ventricles). 15 Treatment for toxoplasmosis in utero and during the first year of life has been shown to significantly improve outcomes.

Rubella is a benign, self-limited viral illness. Since the availability of mass immunization, the reported incidence of rubella has dropped significantly. 16 The prevention of congenital rubella is dependent upon adequate early immunization. Hydrocephalus may be due to leptomeningitis and is a very rare presentation in congenital rubella syndrome with very few cases been reported in literature. 17

CMV is the most prevalent infectious agent causing neurological dysfunction in the developing brain. In addition to the transplacental route, CMV can be transmitted at delivery via the maternal genital tract, breast milk, and in transfused blood products. CMV is easily spread in daycare centers and in young children. Approximately 40% of maternal primary infections are transmitted to the fetus. However, first trimester primary maternal infection is more likely to cause neonatal infection that is evident at birth. Transmission of CMV from the mother to fetus can occur even if the mother was infected long before conception. A meta-analysis of fetal ultrasound findings indicates an association between CMV congenital infection and hydrocephalus in 4.7% of pregnancies. 18 CNS anomalies induced by congenital CMV infection are likely to result from a direct effect of viral replication in the brain and in the placenta. HCP in CMV as a result of ventriculitis and inflammatory infiltrate of T lymphocytes in the
Conclusion:

Preventive activity in high-risk people. Maternal and newborn screening as well as enhance.

It is interesting that neonatal infection occurs far less frequently than might be expected given the high prevalence (one in five) of seropositivity to HSV-2 in childbearing women. Known complications of intraterine HSV infection include seizures, lethargy, irritability, tremors, poor feeding, temperature instability, bulging fontanelle, chorioretinitis, irinac reflex, disorientation, seizures, fever, and death. HSV-2 IgG present in 9.2%. So, HSV-1 IgG present in 26.2%. HSV-2 IgM not found in any case. Whereas HSV-2 IgG present in 9.2%. So, HSV-1 IgG present significantly (P<.05). Literature review indicates relation between congenital HCP and Herpes infection is very weak.

Limitation: This study used serology as a diagnostic tool however Polymerase Chain Reaction (PCR) is more sensitive and specific. Other limitations were that the birth and recruitment interval was not fixed. History regarding immunization of baby, seropositivity of mother and contact with disease person was not recorded.

Proposal: Results of this study is a primary notice, as we face this profound problem we need to focus on this issue by further study. Then we can advice routine maternal and newborn screening as well as enhance preventive activity in high-risk people.
