**Keywords:** Flora; Angiosperms; Lalmai Hill; Cumilla; Bangladesh.

### Abstract

In this study, the vascular flora of the Lalmai hill area of the Cumilla district has been thoroughly explored. This study reveals the occurrence of 923 species of vascular plants under 594 genera and 141 families in the study area, which represents 23.75% of the total 3886 plant species reported from Bangladesh until now. About 68.15% of these species are native and 31.85% are exotic to Bangladesh. Pteridophytes are represented by 30 species belonging to 21 genera and 11 families, whilst Gymnosperms are represented by eight species under seven genera and six families. Magnoliopsida (dicotyledons) comprises 661 species, including four subspecies and two varieties, from 429 genera and 96 families, accounting for 71.54% of the vascular flora of the study area. Liliopsida (monocotyledons) represents 225 species under 137 genera and 28 families, making up 24.35% of this flora. In Magnoliopsida, Fabaceae with 55 species is the largest dicot family, followed by Asteraceae, Malvaceae, Euphorbiaceae, Lamiaceae and Rubiaceae. Most of the species of Liliopsida (68%) are represented by the five families viz., Poaceae, Cyperaceae, Araceae and Commelinaceae. Poaceae with 75 species is the largest monocot family, followed by Cyperaceae, Orchidaceae, Araceae and Arecaceae. The genus *Cyperus* is the largest in the study area. The species *Antidesma roxburghii* Wall. ex Tul. of Phyllanthaceae is rediscovered in Bangladesh. Most of the Magnoliopsida and Liliopsida are herbs (59.80%), which are followed by trees (21.02%), shrubs (17.23%), and palms (1.41%). About 64.57% of the species are recorded as wild, but a significant percentage (27.41%) is planted and cultivated (8.02%). The majority of the species are found to grow in eight categories of habitat viz., roadside, fallow land, homestead, woodland, garden, scrub jungle, agricultural field and grassland. Eight plant species, listed in the Red Data Book of Bangladesh including six as Data Deficient (DD), one Not Evaluated and one Endangered (EN) species, are harboured in the study area. We strongly recommend the adoption of a master plan for minimizing all major threats to the vegetation and habitats of this area and sustainable development, utilization and conservation of its plant resources.

### Introduction

It is essential to have a fundamental understanding of the biodiversity of a country to improve and use its biological resources sustainably and address and mitigate its environmental problems. Taxonomic studies using various non-molecular and molecular data lay the groundwork for understanding and assessing various aspects of plant biodiversity. These studies offer very important and pertinent information and expertise on plant species that are crucial for the confirmation of their identity, description, distribution, origin, evolution, relationship, classification, management and sustainable utilization. Such studies are useful for economic and environmental development based on plant resources, exploration of alternative plant species,

---

\*Corresponding author: E-mail: shetuss@juniv.edu

recognition and conservation of threatened plant species, and assessment, monitoring, and mitigation of the negative effects of climate change on plant species. Due to these consequences, taxonomic studies have been considered pivotal in different regions and nations worldwide for more than a century (Ostertag *et al.*, 2014).

In Bangladesh, a total of 3886 species of vascular plants have been reported through various taxonomic studies conducted sporadically so far (Hossain *et al.*, 2022). These studies were conducted in different forests, regions and small to large administrative areas or small to moderate-sized families at different times since 1814 (Roxburgh, 1814). The plant species composition of many areas or most of the large plant families of this country is still unknown or partially and inadequately known (Hossain *et al.*, 2022; Khan *et al.*, 2021a,b). If adequate floristic surveys are conducted in the remaining areas and large plant families of this country, approximately a further 2000-2500 species of vascular plants might be explored. On the other hand, almost all of the large-scale (Prain, 1903; Siddiqui *et al.*, 2007; Ahmed *et al.*, 2008-2009; Ahmed *et al.*, 2009; Uddin and Hassan, 2018) and many small-scale (Rahman, 2013; Ara *et al.*, 2007; Rahman, 2017; Rashid *et al.*, 2018; Uddin and Hassan, 2010; Malaker *et al.*, 2010; Uddin *et al.*, 2003) taxonomic publications on the flora of this country do not provide information on the specific distribution and voucher specimens of the reported plant species, though some such publication include these kinds of information (Uddin and Rahman, 1999; Islam *et al.*, 2009; Tutul *et al.*, 2010; Rahman *et al.*, 2012; Sultana, 2012; Sarker, 2013; Rahman *et al.*, 2015; Tabassum, 2015; Nahar and Rahman, 2016; Haque *et al.*, 2018; Shetu *et al.*, 2018; Khanam and Khan, 2020; Khanam *et al.*, 2020; Roy and Khan, 2020a,b; Hossain *et al.*, 2021; Khan *et al.*, 2021a,b; Hossain *et al.*, 2022). Therefore, further and adequate floristic surveys involving data collection on specific distribution and voucher specimens of the plant taxa of the unexplored or partially explored areas of this country are very crucial.

The Lalmai hills were once densely wooded and an area near Kotbari was earmarked as a forest belt (BBS, 2013). The vegetation was mainly deciduous and the dominant tree species was *Shorea robusta* C.F. Gaertn (Sal) (Rahman *et al.*, 2001). But in course of the last 20 years, the vegetation of this area has been modified to a semi-deciduous and mixed evergreen category, composed of mostly planted forests associated with many naturally grown plant species and a few small patches of *S. robusta* forest. Almost the whole of Lalmai hills has been cleared up and cultivation has been extended up to the foothills (BBS, 2013). Previously, no floristic or similar other study was carried out on this hill area except enlisting a few plant species in the District Gazetteer of Comilla and the booklet of Ismail and Mia (1973), generating the checklists of 103 undergrowth plant species by Rahman *et al.* (2001), and 151 angiosperms species by Hossain *et al.* (2005), and a hydrobiological study on three different water bodies of this area reporting the occurrence of 352 species of phytoplankton (Bhuiyan, 2022). Most of the habitat-relevant threats to the flora and plant diversity of the Lalmai hill area are functional and have the potential to significantly reduce or change the plant diversity and floristic composition (Ali, 1999; Choudhury, 2002; Khan, 2008; Kulatunga *et al.*, 2012). The hills of this area are going to be destroyed and the hills have already turned to be a hillock on the plain land. The land grabbers carry on their destructive activities. Due to unhindered earth cutting, the deep forest of this area is going to lose its existence.

Therefore, it makes logical sense to perform a thorough floristic study throughout this territory, particularly for understanding the current species composition and diversity, searching the potentially threatened plant species and knowing the changes in plant species composition of the area in course of time and the impacts of climate change, plant resource-based sustainable development, and providing invaluable baseline data necessary for effective conservation of the threatened species as well as assessment and monitoring of the impacts of anthropogenic climate

change on the plants and ecosystems of this area. This study was carried out to provide basic taxonomic information on the vascular plant species extant in the Lalmai hill area, i.e., all hills of Lalmai and their adjacent area, based on detailed floristic inventories and examination of representative specimens.

### Materials and Methods

The Lalmai hill area is a low-amplitude anticline and consists of three toposequence arrangements as hills, piedmonts, and floodplains (Khan *et al.*, 2018; Rahman *et al.*, 2021). This area lies between the latitudes 23°20'N to 23°30'N and longitudes 91°05'E to 91°10'E, at about 8 km westward from Cumilla township (Fig. 1).

The Chittagong-Tripura Fold Belt, particularly the Raghunandan Hill of Indian Tripura Hills, borders this region on the east, the Meghna River on the west, the Gumti River on the north, and the Dakatia River on the south-southeast (Khan *et al.*, 2018). It consists of a north-south elongated low hill range of about 17 km long and 1-2.4 km wide, covering an area of about 33 sq km and locally it is known as the Mainamati-Lalmai range (<https://en.banglapedia.org>).

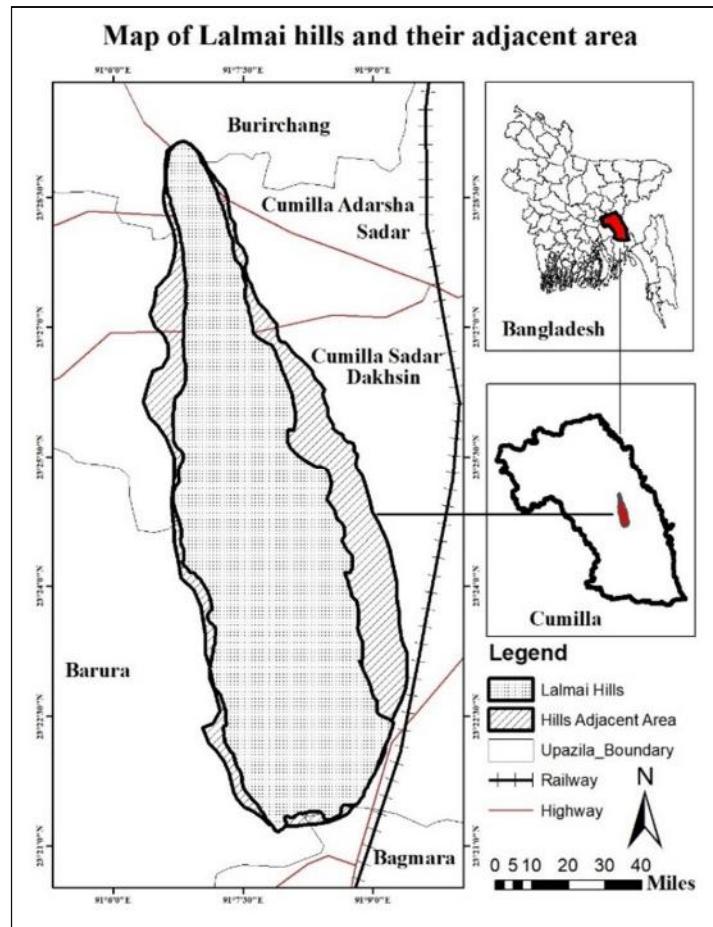

Fig. 1. Location map of the study area.

This hill range is mostly composed of some small to medium-sized hills of about 12 metres in height on average, but the peaks of a few rise up to 52 metres ([www.freemaptools.com/elevation-finder.htm](http://www.freemaptools.com/elevation-finder.htm)). The hills are associated with the faults on the western and eastern sides that are the direct result of the collision of the Indian and Burmese plates (Khan *et al.*, 2018). The eastern half of the hills gradually merges with the surrounding lands and the western section of the hills abruptly transforms into plain land. There are a lot of little hillocks throughout the area. Deeply carved valleys divide some of the hilltops that symbolize the table surfaces. The hill range gradually widens from about 1 km in the north to about 3 km in the south. It is surrounded by the Chandina deltaic plain and drained by three major rivers—the Gumti, the Dakatia, and the little feni (<https://en.banglapedia.org>).

The climate of this region is typically humid tropical with hot, oppressive and mostly cloudy wet seasons and warm and mostly clear dry seasons. A long dry season usually extends from October to May. The hot season lasts from March to June and in this season the maximum temperature ranges from 37°C-39°C (<https://en.banglapedia.org>). The cool season lasts from December to January and in this season the minimum temperature varies from 7°C-10°C. Over the course of the year, the temperature typically varies from 12°C-33°C, the average temperature from 23°C-35°C and the hottest period exists from June to mid-July. The area experiences extreme seasonal variation in monthly rainfall. The rainy period of the year lasts for 10 months, from February to November. The rainless period of the year lasts for two months, from December to January. The average rainfall is 1930-2700 mm, the average humidity is 67%, and about 90% of rainfall appears in the months of May to October (<https://weatherspark.com>). The soil of this area is mostly composed of fine Madhupur clay, which cakes very hard in the dry season (<https://en.banglapedia.org>). It is unconsolidated, finer textured, moderately well-drained, strongly acidic, and low in plant nutrients and droughty. The topsoil is sandy-clay-loam to clay-loam in texture and yellowish-brown in colour. The underlying subsoil is brown to yellowish-red.

This study was carried out in different seasons of 2021-2022. Representative plant specimens were collected, prepared, dried, and preserved using conventional herbarium procedures and techniques (Bridson and Forman, 1989; Singh and Subramaniam, 2008) and stored and studied at Jahangirnagar University Herbarium (JUH). Taxonomic identification of each taxon and collection of data on the uses of plant species in the study area have been done following the approach described in Khan *et al.* (2021a) and Hossain *et al.* (2021). Nomenclatural information, accumulated from relevant literature (Hooker, 1872-1897; Prain, 1903; Wu and Raven, 1994-2001; Wu *et al.*, 1999-2013), are verified by visiting the updated nomenclatural databases (IPNI, 2022; POWO, 2022; TROPICOS, 2022; WFO, 2022). All voucher specimens are preserved at JUH.

The families of Pteridophyta, Gymnosperms and Angiosperms have been arranged following Pichi (1977), Kramer and Green (1990) and Cronquist (1988), respectively, and the genera and species under each family alphabetically. In Magnoliopsida, the families Phyllanthaceae, Putranjivaceae, Linderniaceae and Mazaceae, not included in Cronquist (1988)'s System, are placed beside their close families, *viz.* Euphorbiaceae, Plantaginaceae and Lamiaceae, respectively, whereas, in Liliopsida, the taxa of Liliaceae are placed under three separate families, *viz.* Hypoxidaceae, Amaryllidaceae and Asparagaceae following the APG IV System (Angiosperm Phylogeny Group, 2016). The nativeness of the species was recognized by consulting the relevant literature (Wu and Raven, 1994-2001; Wu *et al.*, 1999-2013; Hossain and Pasha, 2001) and databases (POWO, 2022). The use categories of the species were determined based on the authors' knowledge, consultation with the local people and relevant literature (Ghani, 1998; van Valkenburg and Bunyaphraphatsara, 2001; Siddiqui *et al.*, 2007; Ahmed *et al.*, 2008-2009; Ahmed *et al.*, 2009; Khan *et al.*, 2021a; Annon, 2022; Hossain *et al.*, 2022).

## Results and Discussion

This study documents the occurrence of a total of 923 species of vascular plants under 594 genera and 141 families in the study area. These species constitute about 23.75% of the total 3886 plant species reported from Bangladesh so far (Hossain *et al.*, 2020; Ashrafuzzaman and Sarwar, 2021; Ashrafuzzaman *et al.*, 2022). Pteridophytes were represented by 30 species under 21 genera and 11 families, whereas Gymnosperms by eight species under seven genera and six families. Magnoliopsida (dicotyledons) comprised 661 species, including four subspecies and two varieties, from 429 genera and 96 families, accounting for 71.54% of the vascular flora of the study area, whereas, Liliopsida (monocotyledons) represented 225 species under 137 genera and 28 families comprising 24.35% this flora (Table 1).

The native species of this vascular flora make up about 68.15% (629 species), while the exotic species 31.85% (294 species) of the total. The majority of the species (64.57%; 596 species) were wild, but a significant percentage (27.41%; 253 species) was found as planted and cultivated (8.02%; 74 species). In Pteridophyta, the family Pteridaceae composed of 12 species was the biggest. It was followed by Polypodiaceae with four species, Salviniaceae and Thelypteridaceae three species each. The biggest plant genus in this group was *Adiantum* L. and *Pteris* L. with three species each. In Gymnosperms, Cupressaceae and Cycadaceae representing two species each were the bigger families, and except *Cycas* L., all genera were represented by single species each.

In Magnoliopsida, five families namely Fabaceae, Asteraceae, Malvaceae, Euphorbiaceae and Lamiaceae, represented by 55, 43, 36, 31 and 25 species respectively, comprised 28.74% of species of this group. The families Acanthaceae, Apocynaceae, and Phyllanthaceae were represented by 20 species each, which were followed by Caesalpiniaceae and Cucurbitaceae (18 species each), Amaranthaceae (17 species), Moraceae (16 species), Solanaceae (15 species), Mimosaceae (14 species), Vitaceae (13 species) and Rutaceae and Polygonaceae (10 species each). The genus *Euphorbia* L. composed of 12 species was the largest and followed by *Ficus* L. (10 species), *Solanum* L. (eight species), *Hibiscus* L. (seven species), *Persicaria* (L.) Mill. and *Phyllanthus* L. (six species each), *Albizia* Durazz., *Brassica* L., *Syzygium* P. Browne ex Gaertn., *Senna* Mill., *Sida* L., *Terminalia* L., and *Ipomoea* L. (five species each), and *Amaranthus* L., *Artocarpus* J.R. Forst. & G. Forst., *Bougainvillea* Comm. ex Juss. *Cissus* L., *Torenia* L., *Vigna* Savi, and *Ziziphus* Mill. (four species each).

Most of the species of Liliopsida (68%, 153 species) were represented by the five families *viz.*, Poaceae (75 species), Cyperaceae (31 species), Araceae (21 species) and Arecaceae and Commelinaceae (13 species each), which were followed by the families Amaryllidaceae, Asparagaceae and Zingiberaceae (eight species each), Orchidaceae (seven species) and Dioscoreaceae and Hydrocharitaceae (five species each). The genus *Cyperus* with 16 species was the largest, which was followed by *Panicum* L. (eight species), *Fimbristylis* Vahl (six species), *Dioscorea* L. (five species), and *Commelina* L., *Eragrostis* Wolf, *Murdannia* Royle and *Dracaena* Vand. (four species each).

A total of 552 species (59.80%), of this flora and most of the Magnoliopsida and Liliopsida were herbs, 159 (17.23%) shrubs, 194 (21.02%) trees, 13 (1.41%) palms and five (0.54%) bamboos (Table 1). The majority of the herbaceous species were erect (56.34%), which was followed by climber (16.85%), prostrate (15.40%), epiphyte (2.36%), creeper (4.17%) and others (floating, submerged and parasite etc.). Other habit categories included submerged, rooted floating, free-floating, prostrate and parasite. Among the shrubs, most were erect (132 species, 83.02%), which was followed by scandent (18 species, 11.32%), liana (6 species, 3.77%), and parasites (three species, 1.89%).

Abdur Rahim, SSS- Shayla Sharmin Shetu.

In the study area, the majority of the species were found to grow in eight categories of habitat *viz.*, Roadside (37.16%), fallow land (34.24%), homestead (26.54%), woodland (20.48%, garden (18.85%), scrub jungle (16.14%), agricultural field (14.08%) and grassland (12.89%), followed by other habitat categories namely, wetland (9.32%), hill slope (9.21%), forest margin (5.42%), hilltop (5.42%), other plants (2.28%), and brick wall (0.43%) (Fig. 2).

The majority of the species were reported as medicine (61.54%), which was followed by ornamental (24.27%), livestock feed (9.53%), vegetable (9.10%), fuel wood (7.91%), fruit (7.04%), timber (6.07%), soil binder (4.33%), fibre (3.36%) and green manure (2.93%), which are the major produces of the study area (Fig. 3). The plant species used as dye-yielding (1.63%), oil-yielding (1.52%), hedge (1.41%), handicrafts (1.30%), spice (1.19%), timber (1.19%), pulse (0.98%), aquarium plant (0.76%), poison (0.65%), edible (0.54%), juice (0.43%), perfume (0.33%), paper pulp (0.22%), cosmetics (0.22%) and refreshment (0.11%) were the minor produces of the study area.

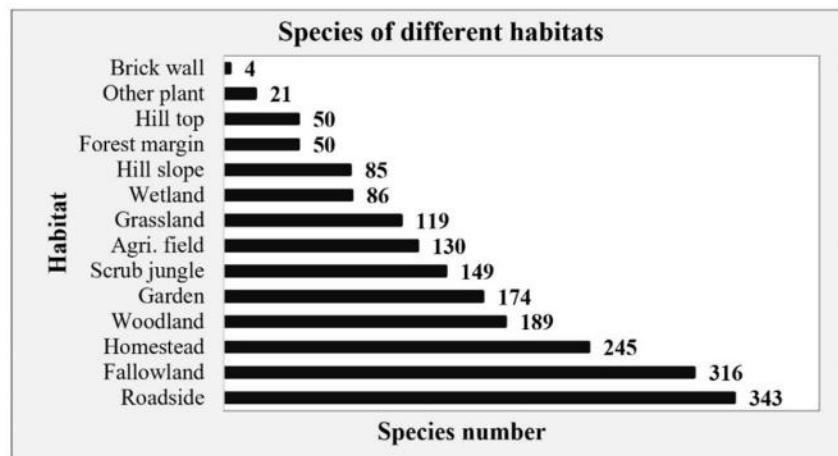

Fig. 2. Plant species in different habitats of Lalmai hill area.

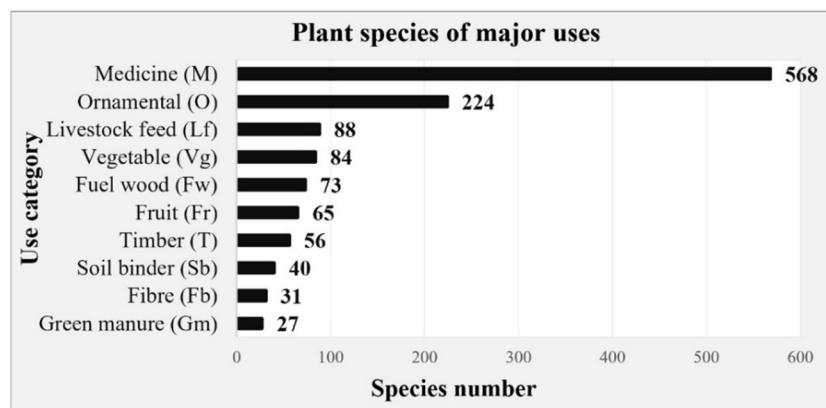

Fig. 3. The major economically important species of Lalmai hill area.

The study area harbours eight plant species, six of which are listed as Data Deficient (DD), one as Not Evaluated (NE) and one as Endangered (EN) (Khan *et al.*, 2001; Ara *et al.*, 2013). These species are *Andrographis paniculata* (Burm.f.) Nees (DD), *Anisoptera scaphula* (Roxb.) Kurz (DD), *Aquilaria malaccensis* Lam. (DD), *Calamus erectus* Roxb. (DD), *Glochidion heyneanum* (Wight & Arn.) Wight (EN), *Mangifera sylvatica* Roxb. (NE), *Swintonia floribunda* Griff. (DD) and *Tectaria chattogrammica* Ching (DD). All of these species were found as planted except *A. paniculata* and *T. chattogrammica* which were observed as common and naturally regenerated and *G. heyneanum* which was rare in this area.

A comparison in the plant species composition of the study area (Lalmai hills and their adjacent area) with that reported previously from some localities of this country, composed of similar kinds of habitats, indicates that the number of species per square kilometre found in the study area is nearly similar to that of Rajkandi Reserve Forest (Haque *et al.*, 2018), Hazarikhil Wildlife Sanctuary (Rahman, 2017), somewhat higher than that of Sitakunda Ecopark (Islam *et al.*, 2016), Satchari National Park (Arefin *et al.*, 2011), Baraiyadhala National Park (Rashid *et al.*, 2018), and Teknaf Wildlife Sanctuary (Uddin *et al.*, 2013) but lower than those reported from Jahangirnagar University Campus (Khan *et al.*, 2021a) and Lawachhara National Park (Uddin and Hassan, 2010) (Fig. 4).

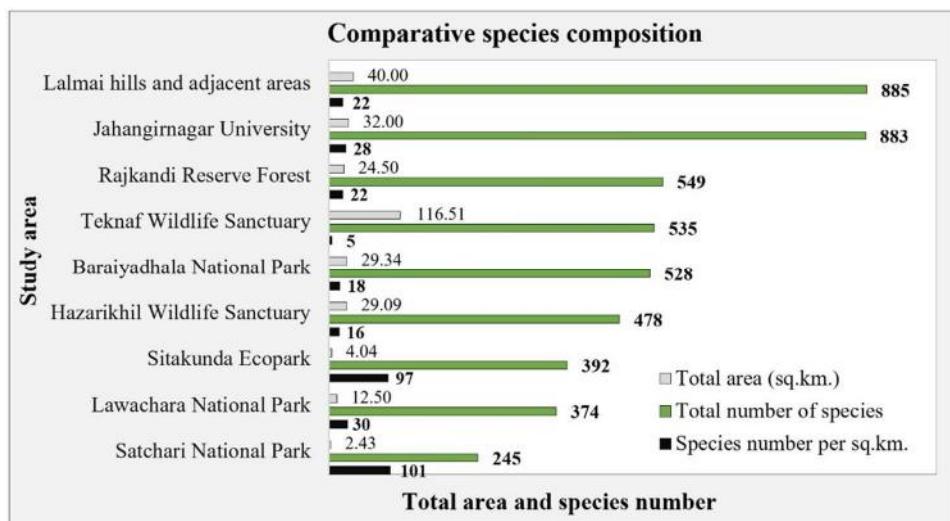

Fig. 4. Comparison of Lalmai hill area with some pertinent localities of Bangladeshi plant species composition.

Rahman *et al.* (2001)'s recorded 24 species of Lalmai hills were not found to occur there during this study. These species belong to the families Annonaceae (one species), Apocynaceae (one species), Asteraceae (one species), Commelinaceae (one species), Convolvulaceae (one species), Euphorbiaceae (one species), Fabaceae (three species), Lamiaceae (two species), Passifloraceae (one species), Phyllanthaceae (two species), Poaceae (two species), Polygalaceae (one species), Polypodiaceae (one species), Rubiaceae (five species), and Zingiberaceae (one species). Similarly, 17 species belonging to the families Acanthaceae (one species), Apocynaceae (two species), Cyperaceae (one species), Elaeocarpaceae (one species), Fabaceae (four species), Lamiaceae (one species), Myrtaceae (one species), Phyllanthaceae (one species), Poaceae (three

species), Primulaceae (one species) and Solanaceae (one species) reported by Hossain *et al.* (2005) from this area were not found during this study. A reason for the absence of these species in the study might be their direct missing due to habitat destruction and other anthropogenic activities. Another reason seems to be the incorrect identification of the species that could not be verified due to the lack of their voucher specimens.

Traditionally, the study area is being gradually converted from a natural deciduous forest area to a semi-urban area covered with cultivated, planted and natural plant populations. Currently, about 20%-25% of the area is already converted into a semi-urban area housing some infrastructures including a few institutions and a part of the regional cantonment. A notable part of the remaining area is notably disturbed through various anthropogenic activities including different plantation and cultivation programs following repeated vegetation clearing and habitat destruction. However, a huge number of plant species, as enumerated by this study, have been established in this area through the introduction of many exotic species (31.12% of the flora), mainly in the semi-urban localities including gardens, campuses, roadsides, tourist spots etc. and the introduction of diaspores of different plant species from different regions of the country through various biotic and abiotic agents. Some parts of the area, composed of roadside, fallow lands, homesteads, woodlands, gardens, and agricultural fields, are covered with dense vegetation.

The vegetation of the study area provides habitats for various animal groups (wildlife). The biodiversity of the study area is affected by different kinds of threats, mostly resulting from multifarious anthropogenic activities including hill clearing and cutting, land grabbing, agricultural expansion following vegetation clearing, infrastructure development, settlement, firing, grazing, leaf litter and fuel wood collection, and huge visits etc. are recognized as the major threats to its biodiversity. However, this area is harbouring a rich biodiversity with a huge number of plant species in its diverse ecosystems. As an original site of natural vegetation, this area might be an excellent choice for *in situ* and *ex situ* biodiversity conservation.

Therefore, we strongly recommend the adoption of a master plan for minimizing all major threats to the vegetation and habitats of this area and sustainable development, utilization and conservation of its plant resources. In order to implement this plan, strengthening and improving the existing management of the area by adopting necessary conservation initiatives including effective policies, and legislation, adopting and strict enforcement of the necessary laws of natural resource utilization including lands, controlling and minimizing anthropogenic interferences, increasing public awareness, improving the quality of major natural habitats are highly recommended. We highly advise routine inventories and monitoring programs for this area's biodiversity. Adequate protection, conservation and development of the diminishing natural resources of this area including its biodiversity will improve its sustainable socio-economic and ecological services.
