ABSTRACT

This research was intended to evaluate the antiradical activity of extracts and fractions of rambutan seed using 2,2'-diphenyl-1-picrylhydrazyl (DPPH) and 2,2'-azinobis-(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS⁺). The powder of rambutan seed was subjected to maceration with methanol. The methanolic extract obtained was then fractionated using petroleum ether (PE), dichloromethane (DCM) and ethyl acetate (EA) to obtain PE, DCM and EA fractions, respectively. The methanol extract and fractions were then assayed for antiradical activities and phenolics and flavonoid contents. The results showed that EA fraction has lowest IC₅₀ values among extract and fractions evaluated, i.e. 244.6 ± 2.1 µg/ml using DPPH radical. Using ABTS radical, EA fraction (0.1%) also revealed the highest antiradical activity of 643.4 ± 34.9 µM trolox equivalent. However, these antiradical activities were lower than those in positive controls used (vitamin C and vitamin E). The antiradical activities of extract and fractions correlated with total phenolics and flavonoid contents. The seed of rambutan fruit could be exploited as natural antioxidants to be used in food supplements.

Key words: Rambutan seed, antiradical activities, DPPH, ABTS, phenolics contents.

INTRODUCTION

Oxidative stress was caused by imbalance between the endogenous antioxidants and species reactive of oxygen (ROS) and nitrogen (RNS).¹ Free radicals could be formed during the interaction of ROS/RNS with various biological components such as lipids and proteins.²⁻⁴ The imbalance between ROS/RNS and antioxidants is believed to lead to degenerative diseases such as diabetes, cancer and atherosclerosis.⁵⁻⁷ Therefore, human body needs exogenous antioxidants to neutralize free radicals.

Antioxidants are groups of compounds having the capability to delay or prevent the oxidation reactions of biological components (lipids, proteins, nucleic acids) by retarding initiation and/or propagation

reactions of free radical.⁸ Based on its sources, antioxidants can be classified as natural antioxidants (coming from plants) and synthetic antioxidant coming from chemical synthesis. Some publications reported the negative effects of synthetic antioxidants. As a consequence, the need for natural antioxidants has increased currently because of the consumer concerns on safety issues.¹⁰ The exploration of antioxidants from underutilized part of fruit such as rambutan peel¹¹ and mango peel¹² was highlighted in order to reduce plant wastes.

Antioxidants isolated from plants are mainly coming from phenolics and flavonoids contents, therefore, evaluation of antioxidant activities is frequently correlated with the total contents of phenolics and flavonoids.^{13,14} Among antioxidant assay, radical scavenging methods is the most commonly used for antioxidant screening of plant

extracts.¹⁵ In this study, the antiradical activities using DPPH and ABTS and its correlation with phenolics and flavonoid contents of extract and fractions of rambutan seed have been evaluated.

MATERIALS AND METHODS

Materials. Rambutan fruit was obtained from several locations in South Konawe, the province of Southeast Sulawesi, Indonesia. The fruit authenticity was performed in Department of Pharmaceutical Biology, Faculty of Pharmacy, Gadjah Mada University (UGM), Yogyakarta. The radicals of 2,2-diphenyl-1-picrylhydrazyl (DPPH) and 2,2'-azinobis(3-ethylbenzo thiazoline-6-sulphonic acid) diammonium salt (ABTS) were obtained from Sigma (Aldrich, USA). Trolox or 6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid, Folin-Ciocalteu reagent, gallic acid, and potassium persulphate were bought from E. Merck (Darmstadt, Germany). The other solvents and reagents used were of analytical grade.

Preparation of extract and fractions of rambutan seed. Preparation of extract and fractions of rambutan seed was carried according to Rohman *et al.*¹⁵ The rambutan seed was cut into small pieces using commercial cutter, and subjected to drying using conventional oven at 65°C for 2 days until dry and then powdered. The powder of rambutan seed

was subjected to maceration with methanol (1: 10) for four days. The macerate was then filtered, and residue was then re-macerated for 2 days. The filtrates from two times of maceration were evaporated using vacuum rotary evaporator to obtain methanol extract. Furthermore, the methanolic extract was added to warm distilled water and then fractionated using petroleum ether (PE), dichloromethane (DCM) and ethyl acetate (EA) to get the corresponding fractions. The initial methanolic extract and the fractions (PE, DCM, EA and water) were used for antiradical assay as well as for determination of phenolics and flavonoid contents.

Evaluation of antiradical assays. Antiradical activities of extract and fractions of rambutan seed was evaluated using two radicals, namely 2,2-diphenyl-1-picrylhydrazyl (DPPH) and 2,2'-azinobis(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS^{•+}). For DPPH assay, 1.0 ml DPPH 0.4 mM in methanol was mixed with 50 µl of extract or fractions at different concentrations and 3.950 ml methanol (total volume of 5 ml). A control solution was prepared by adding 1 ml of DPPH (0.4 mM) with 4 ml methanol. After 20 minute of operating time, the absorbance values were read at 517 nm using calibrated UV-Vis spectrophotometer against blank methanol.

$$\% \text{ Radical scavenging} = \frac{(\text{Abs control} - \text{Abs sample})}{\text{Abs control}} \times 100$$

The DPPH radical activity was expressed with IC₅₀, defined as the concentration of the samples needed to cause 50% scavenging of DPPH radical, calculated by an equation generated from linear regression.¹⁶ Vitamin C (ascorbic acid) and vitamin E (tocopherol) were used as positive controls. For ABTS assay, ABTS (7 mM) and potassium persulphate (2.45 mM) were mixed in ratio 1:1 and allowed to stand in the dark for 12-16 hrs to produce stock solution of ABTS radical cation (ABTS^{•+}). This solution was further diluted with methanol to attain absorbance of 0.600-0.800 at 734 nm. The ABTS^{•+} working solution (3 ml) and 30 µl of blank,

standard or sample were mixed and the absorbance was measured at 734 nm after 6 min using a spectrophotometer. The blank was run with methanol. A standard curve was prepared using Trolox solution (0.3-1.5 mM).¹⁷

Determination of phenolics and flavonoid contents. Both total phenolics and flavonoid contents were determined using calibrated visible spectrophotometer. Phenolics were read at 750 nm after reaction of samples with Folin-Ciocalteu reagent.¹⁸ Total phenolic contents were calculated as gram gallic acid equivalent/100 gram of dry samples. For flavonoid contents, the samples were reacted

with aluminum chloride and measured at 512 nm.¹⁹ Total flavonoid contents of extract and fractions were expressed as gram of rutin equivalent/100 gram dry material.

Data analysis. All data of antiradicals and its related data were analyzed in triplicate and expressed as mean \pm standard deviation using Excel (Microsoft Inc., USA).

RESULTS AND DISCUSSION

Among antioxidant assays, the use of reactive radicals scavenged by active compounds is the most popular methods reported by some authors. Two radicals are typically used, namely 2,2'-diphenyl-1-picrylhydrazil (DPPH) radical and 2,2'-azinobis(3-ethylbenzo thiazoline-6-sulphonic acid) diammonium salt cation radical (ABTS⁺). Any compounds capable of scavenging both radicals could be taken into account as antioxidant. The main requirement of samples to be active as radical scavengers is the capability to give hydrogen radicals into DPPH or ABTS. Typical compounds that meet this requirement are phenolics and flavonoids. The

reduction of colour intensity of both radicals due to addition of evaluated samples indicated that studied samples can act as radical scavengers.²⁰ Figure 1 compiled IC₅₀ values of extract and fractions of rambutan seed using DPPH assay. The lower the IC₅₀, the higher the antiradical activities. EA fraction has the lowest IC₅₀ indicating that it was the most active antiradicals in DPPH assay. However, the antiradical activities of studied extracts and fractions were lower than those of vitamin C with IC₅₀ of 3.70 \pm 0.05 μ g/ml and vitamin E with IC₅₀ of 2.65 \pm 0.04 μ g/ml.

The antiradical activity of samples using ABTS radical was expressed as Trolox equivalent as in figure 2. Among the evaluated samples, ethyl acetate fraction exhibited the highest Trolox equivalent with value of 729 μ M compared with other extract and fractions. This indicated that EA fraction had highest antiradical activities compared with others. In order to isolate the active compound responsible for antiradical activities, EA fraction was subjected to further fractionation.

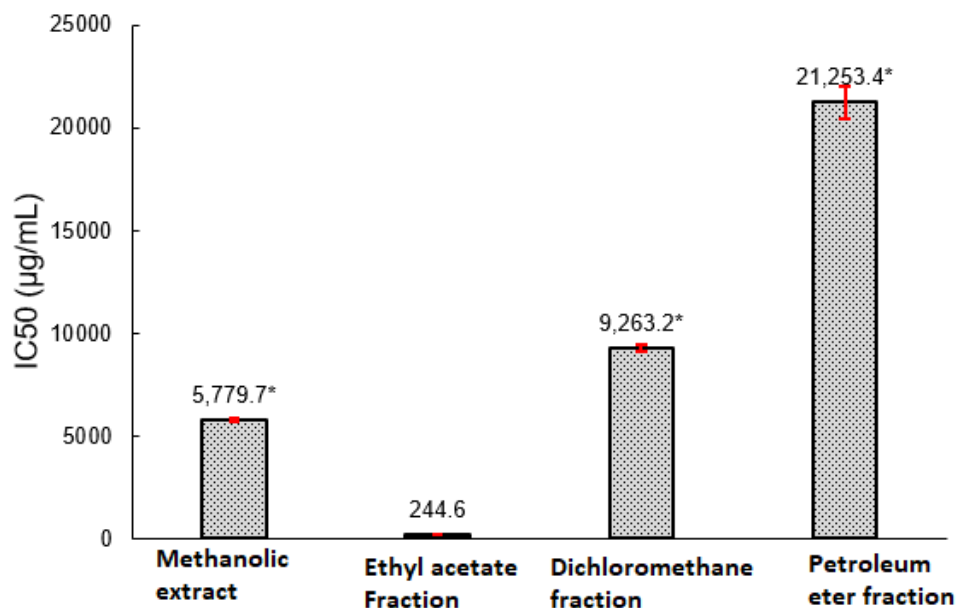

Figure 1. The IC₅₀ values of methanolic extract and its fractions of Rambutan peel using DPPH radical assay.

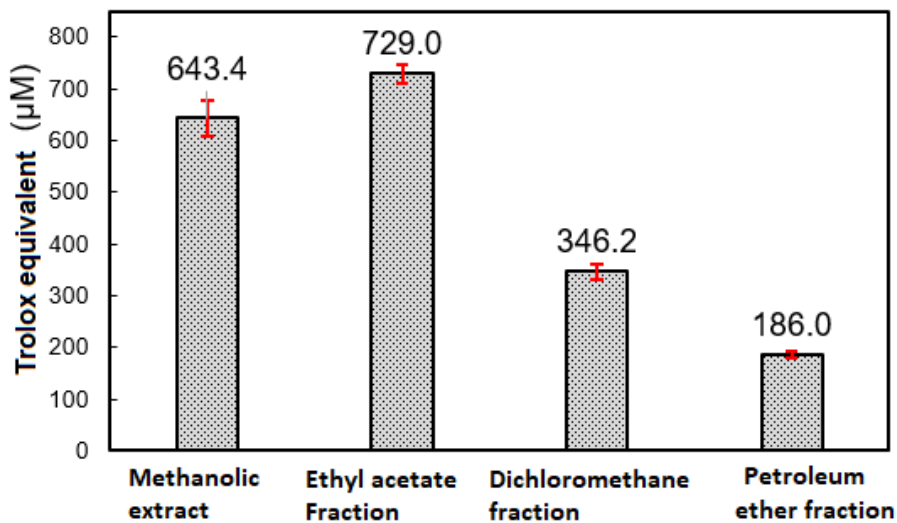

Figure 2. The antiradical activities of methanolic extract and its fractions using ABTS radical, as expressed with Trolox equivalent.

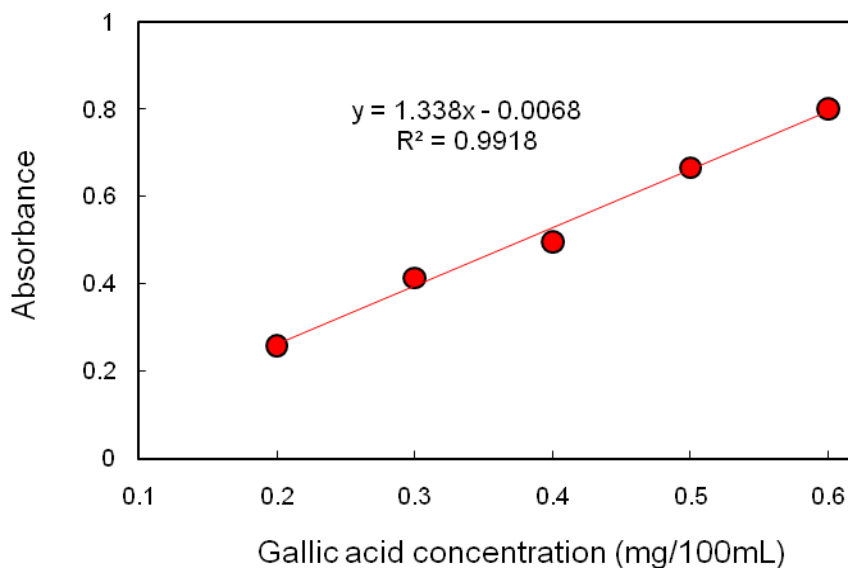

Figure 3. The correlation between gallic acid concentration (x-axis) and its absorbance after reaction with Folin Ciocalteu reagent.

Phenolics and flavonoids are believed to be responsible for antiradical activities due to its capability to donate hydrogen radicals into ABTS and DPP radicals. As a consequence, antioxidant activities from natural sources are correlated with the total phenolics and flavonoids contents. Figure 3 revealed the calibration curve describing the relationship between gallic acid concentration, used as phenolics standard (x-axis) and its absorbances due to reaction between gallic acid and Folin

Ciocalteu reagent (y-axis). The coefficient of determination was 0.9918 indicating that the linear regression equation was acceptable for predicting phenolic contents. The phenolic contents were expressed as gallic acid equivalent (GAE) in 100 g samples of extract and fractions.

The phenolic contents of methanolic extract and its fractions are shown in figure 4. EA fraction exhibited the highest phenolics content (0.072% GAE), compared to others. This result was in

agreement with antiradical activities, in which EA revealed the highest antiradical activity. This supported the correlation between phenolics contents and antiradical activities either with DPPH or ABTS radicals.

Figure 5 revealed the correlation between phenolics contents and antiradical activities using DPPH (A) and ABTS (B). The linear regression equation obtained for the correlation between total phenolic content (TPC) (x-axis) with IC_{50} values (y-axis) has R^2 of 0.69576, which showed that 69.58% of

DPPH radical scavenging activities were from contribution of phenolic compounds and the other contribution come from other compounds, indicating moderate correlation between IC_{50} values and TPC.²⁰ The higher R^2 value was obtained for the relationship between TPC and antiradical activities using ABTS radicals, i.e. 0.81828. This indicated that phenolic compounds present in rambutan peel were more active toward ABTS radical than DPPH radicals, however, the individual phenolics responsible for these activities have not been reported yet.

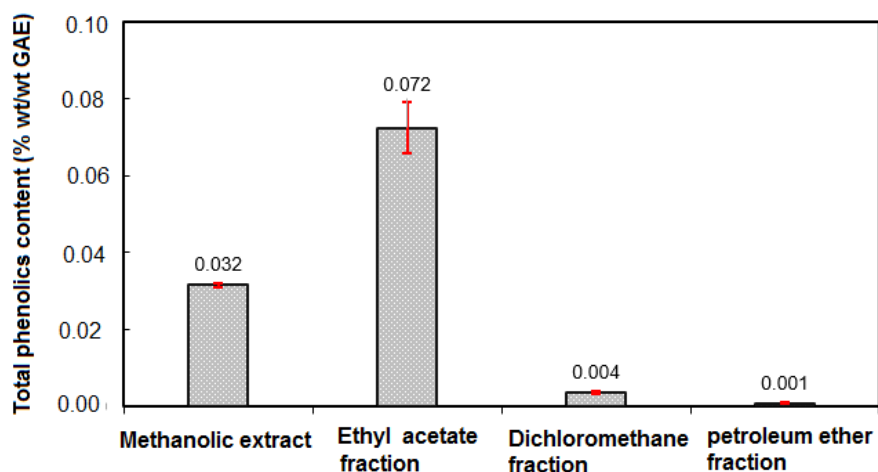

Figure 4. The phenolics content of methanolic extract and its fractions of Rambutan seed, expressed as % wt/wt gallic acid equivalent.

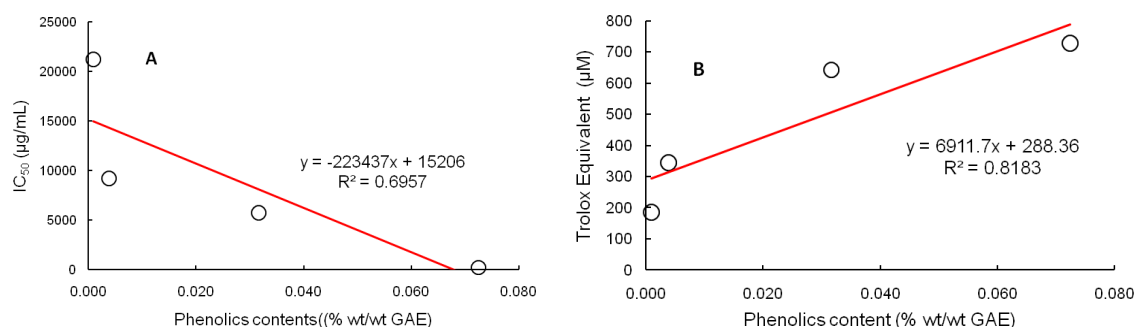

Figure 5. The correlation between phenolic content and antiradical activities of methanolic extract of rambutan seed and its fractions using DPPH (A) and ABTS (B).

Figure 6A showed the relationship between rutin concentration, used as flavonoid standard (x-axis) and its absorbances due to reaction with $AlCl_3$ followed with $NaOH$. The R^2 was found to be 0.9947 indicating the linear regression equation was acceptable for predicting flavonoid contents. EA

fraction also had the highest flavonoid contents, i.e. 4.98% wt/wt rutin equivalent (RE), among extract and fractions evaluated, therefore it is interesting to correlate between flavonoid contents and radical activities.

Figure 7 revealed the correlation between the total flavonoid content (TFC) (x-axis) and antiradical activities, using DPPH radicals (A) and ABTS radicals (B). Using DPPH radicals, R^2 found was 0.47326, indicating that 47.33% of DPPH radical scavenging activity came from the contribution of

flavonoid content. Using ABTS radicals, the correlation between TFC and Trolox equivalent had R^2 of 0.46736, which showed that 46.74% of ABTS radical scavenging was from the contribution of flavonoid compounds.

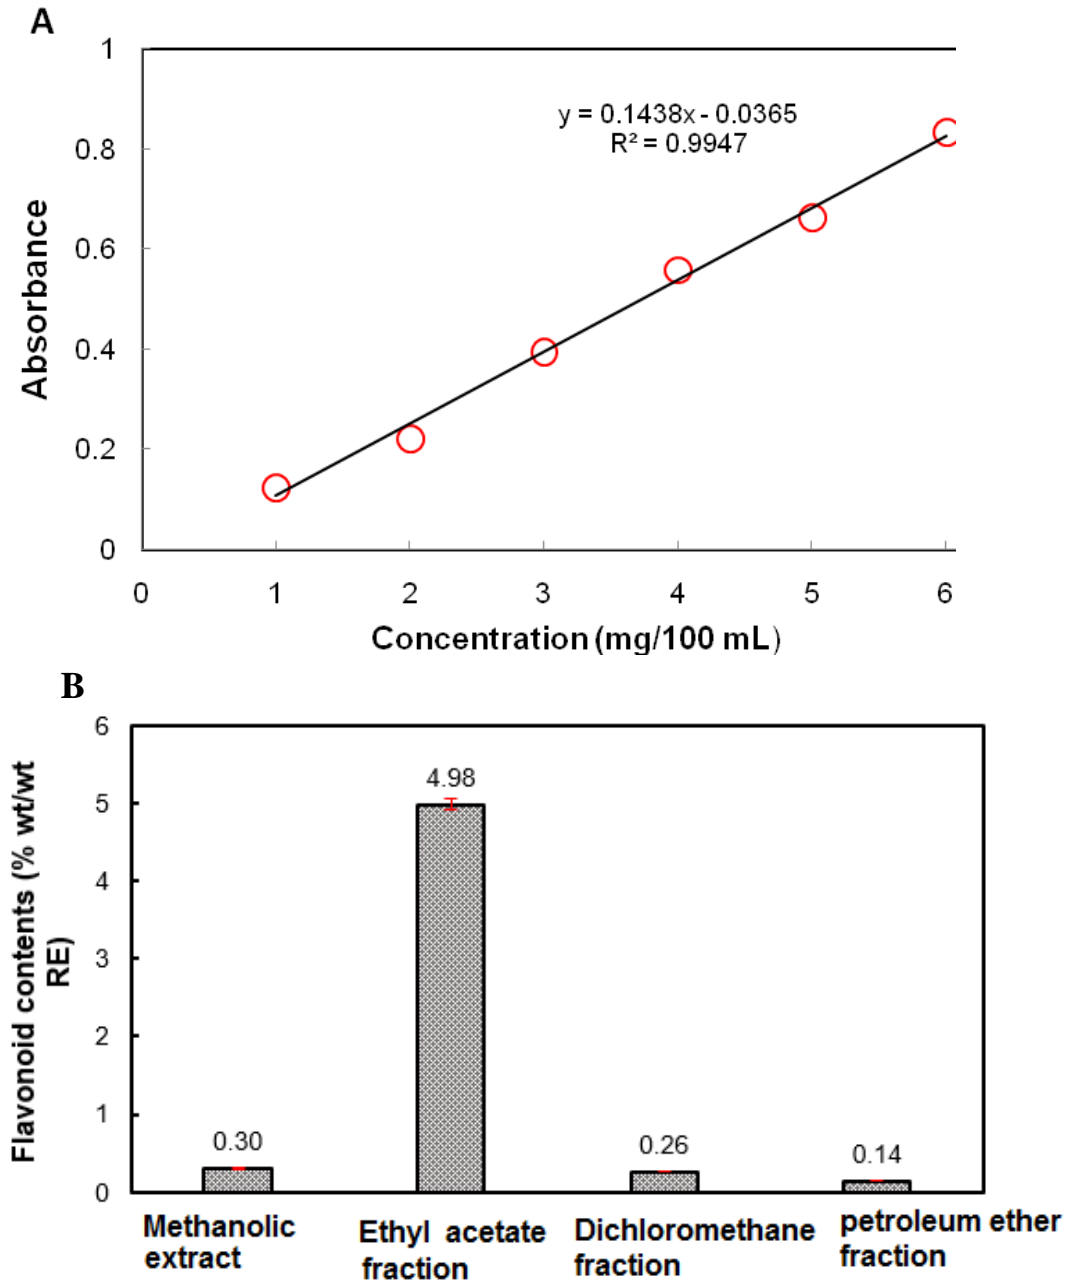

Figure 6. The correlation between rutin concentration (x-axis) and its absorbance (A) and the flavonoid contents of methanolic extract of Rambutan seed and its fractions, expressed as % wt/wt rutin equivalent.

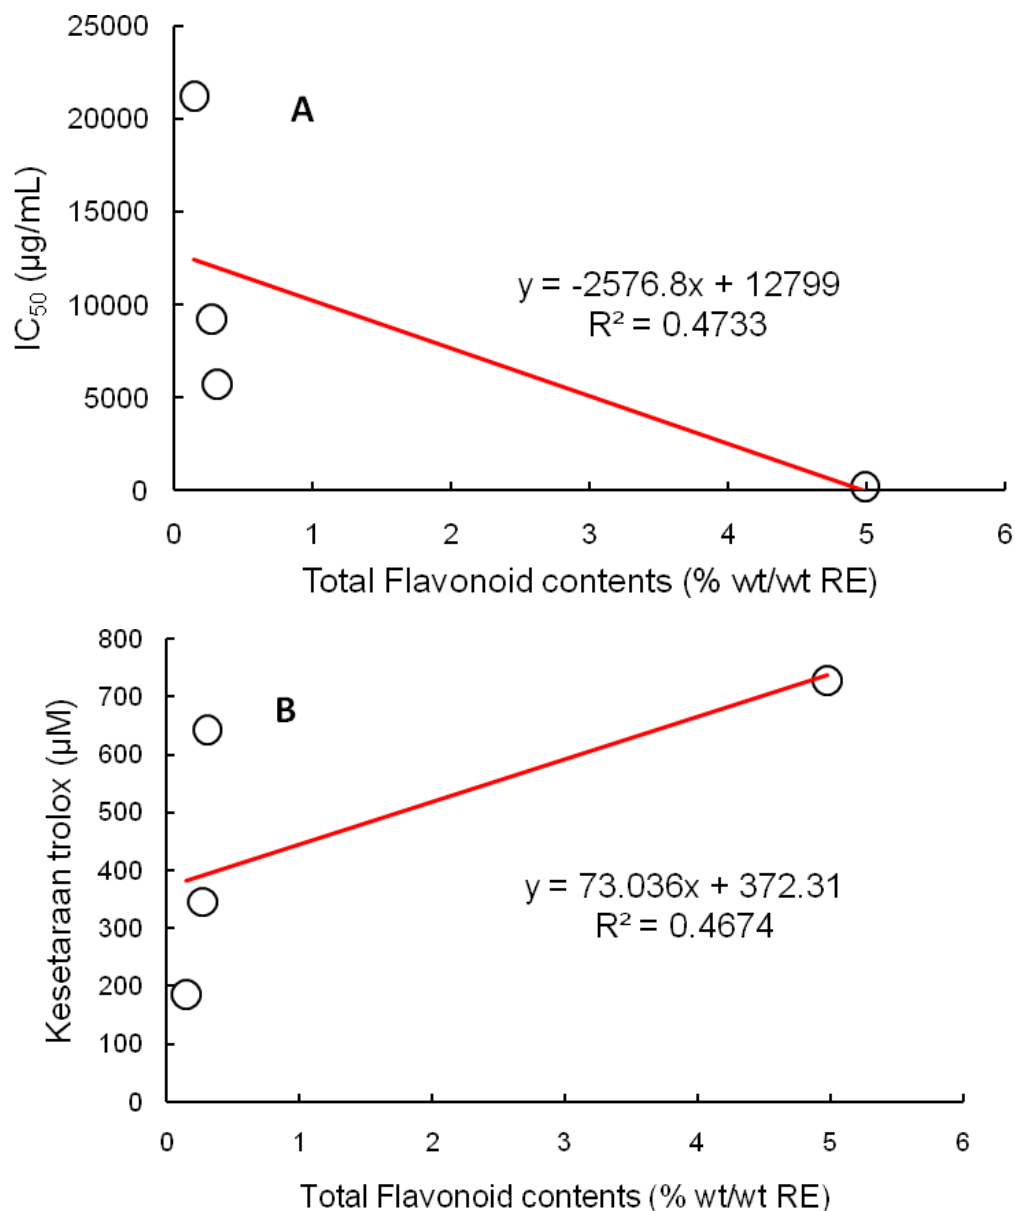

Figure 7. The correlation between flavonoid content and antiradical activities of methanolic extract of rambutan seed and its fractions using DPPH (A) and ABTS (B).

CONCLUSION

Among methanolic extract and its fraction of rambutan seed, the ethyl acetate soluble fraction has the most antiradical activities using both DPPH and ABTS radicals. These antiradical activities were correlated with total phenolic and flavonoid contents. Oleic acid was among compounds identified in ethyl acetate fraction.
